ABSTRACT

Parkinson’s disease (PD) is a neurodegenerative disease whereby there is the characteristic progressive degeneration of dopaminergic neurons in the substantia nigra pars compacta (SNpc) leading to motor deficiencies. The 1-methyl-4-phenyl-1, 2, 3, 6-tetrahydropyridine (MPTP), is the neurotoxin that was used to induce the mice to be models of PD. Thunbergia laurifolia Lindl. (TL) is a Thai herbal medicine which is used for reducing the effects of toxins. This study aims to find out whether TL leaf extract can prevent the onset of PD motor impairments due to MPTP by using pre TL and post TL treatments and observing the mouse’s latency times on the Rotarod test, the frequency of movements on the Motor Activity Test, and the numbers of the dopaminergic neurons on the tyrosine hydroxylase immunoreaction (THir+) The results showed that the latency times and motor activity of the pre TL treated group were significantly higher than that of the pre-vehicle treated group at P < 0.01. On the other hand, there was no difference between those of the post TL and the post vehicle treated groups. The number of THir+ neurons of pre TL and post TL treated groups were significantly higher than that of their vehicle
treated groups, yet the number of the pre TL treated group was less different ($P < 0.05$) than that of the post TL treated group ($P < 0.01$) when compared with the control. In conclusion, we have determined that the pre-treatment of TL extract in the MPTP mouse model of PD alleviates motor impairments.

**INTRODUCTION**

Parkinson’s Disease (PD) is a chronic progressive neurodegenerative disorder that occurs when there is a dopaminergic neuronal loss in the substantia nigra pars compacta (SNpc). It is characterized by motor abnormalities including tremors, muscular rigidity, bradykinesia, and postural abnormalities (Jankovic, 2008). The most common toxin which is used for inducing PD in animal models is 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) (Philippens et al., 2010; Tieu, 2011; Blandini and Armentero, 2012; Kasahara et al., 2013). This toxin endangers the dopaminergic neurons in the SNpc leading to dopaminergic neurotransmitter synthesis loss occurrences that are found in PD. It was found that the dopaminergic neurons in SNpc in PD had decreased which is indicated by the presence of immunoreactive tyrosine hydroxylase (THir+) cells (Kozina et al., 2014; Alam et al., 2017). The motor function and behavior of animals with PD are accessed by Rotarod and Motor Activity Tests which are found to be significantly different from those of normal animals (Hutter-Saunders et al., 2012).

*Thunbergia laurifolia* Lindl. (TL) or “Rang chuet” is known as a Thai herb medicinal plant which is well known for its detoxification qualities. TL is used to treat poisonings that can occur from insecticides, arsenic, alcohol, chemicals, drugs, food, and water (Junsi and Siripongvutilorn, 2016). Usanawarong et al. (2000) indicated that aqueous TL leaf extract can reduce toxicity in paraquat intoxicated rats. Tangpong and Satarug (2010) also found that TL leaf extract attenuated the neuronal degeneration in the hippocampus and restored memory loss of lead intoxicated rats. Not only is it used detoxify poisons, TL also has several pharmacological properties being an anti-inflammatory, an anti-oxidant, an anti-microbial, and an anti-nociceptive agent (Chan et al., 2011; Boonyarikpunchai et al., 2014). Thongsaard and Marsden (2013) found that TL extract increased extracellular dopamine levels in striatum.

The acute MPTP mouse model of PD was induced by intraperitoneal injections (i.p.) of MPTP at 20 mg/kg of body weight (BW), 4 times every 2 hours, as has been done in previous study (Lee et al., 2017). This model of PD represents the earliest phase of PD which is indicated by having 53% of the dopaminergic neurons compared to that of a normal subject (Pain et al., 2013), and having a 40% to 90% deficiency in dopamine neurotransmitters (Jackson-
Lewis and Przedborski 2007). The acute model of PD has been used to study the neuroprotective effects and properties for improving motor abnormalities using ‘Jitai Tablet’, a traditional Chinese medicine (Liu et al., 2014) and “Combretum leprosum mart”, a Brazilian medicinal plant (Moraes et al., 2016). However, these properties have not yet been studied using Thai medicinal plants such as ‘Rang chuet’. We hypothesize that the TL extract could prevent the occurrence of Parkinson’s disease in mouse induced by MPTP. We investigated whether TL extract is a protective agent for attenuating the motor dysfunction and neuronal degeneration in the MPTP mouse model of PD.

MATERIALS AND METHODS

Preparation of Thunbergia laurifolia Lindl. (TL) leaves extracts

Fresh TL leaves were harvested from an area in Sing Buri Province, Thailand. Its dried form was collected as a voucher specimen (QBG. No. 104862) and was stored at Queen Sirikit Botanic Garden Herbarium (QBG), Ministry of Natural Resources and Environment, using the scientific name that was identified at Ethnobotany and Northern Thai Flora Laboratory, Department of Biology, Faculty of Science, Chiang Mai University. The fresh TL leaves were thoroughly washed and dried in a hot-air oven at 40-50 °C for 2-3 days, or until the leaves had completely dried. The dried leaves were ground into a fine powder. The powder was extracted with absolute ethanol. The container of the extract solution was put into a shaker set at slow speed for 4 hours every 4 days. The crude TL extract solution was filtered using Whatman No. 1 filter paper. The sample of the TL extract solution was analyzed for the total anti-oxidant agents as 106.0 mg/L and total phenolic compounds 290.59 µg/ml by the Research Laboratory for Analytical Instrument and Electrochemical (AIE). The final solution of the TL extract was dried in a rotary evaporator (Heidolph model. MX07R-20-HD2E, USA), and then was lyophilized in a freeze dryer. The dried TL extract was diluted with Tween 80 solution before being used as a dilution of 200 mg/ kg of BW. The rest of dried TL extract was stored at -20 °C.

Animal and experiment protocol

A total of 30 male C57BL/6 mice (Nomura Siam International, Thailand), aged 5 weeks weighing between 20-25 g., were used. All mice were caged in controlled conditions having a cycle of 12 hours of darkness and 12 hours of light with temperature set at 25 °C. They were allowed free access to food and water. The study protocol was approved by the Animal Ethics Committee of the Faculty of Medicine, Chiang Mai University (Approved Protocol No. 26/2560).

The mice were randomly divided into 5 groups (n=6): (1) control group; mice received saline via an IP injection, (2) MPTP + pre Tween 80 group; mice received Tween 80 as a “vehicle” before the MPTP injection (3) MPTP + pre TL group; mice received TL extract before the MPTP injection, (4) MPTP + post
Tween 80 group; mice received Tween 80 after MPTP injection and (5) MPTP + post TL group; mice received TL extract after the MPTP injection.

Mice in this study were induced to be the acute model of PD on day 8 of the experimental period of 15 days by the IP injections of the MPTP at 20 mg/kg of BW, 4 times every 2 hours as done by Lee (2017). For the pre-treatment strategy, the i.p. injection of TL extract with a dilution of 200 mg/kg of body weight and Tween 80 of the same volume were given to the mice for one week (day 1-7) before the MPTP injection. For post treatment strategy, the TL extract and Tween 80 were given to mice for 1 week (day 8-14) after the last dose of the MPTP inducing (Figure 1). All mice were tested for their motor co-ordination and motor movement using the Rotarod Test and Motor Activity monitor or the Open Field Test, respectively. The latency times on the rotarod and the motor activity, or frequency of movement were recorded at day 0, day 7 (one day before the MPTP IP injection), day 9 (one day after the MPTP IP injection), and day 15 (one week after the MPTP IP injection). All mice were sacrificed on the following day and their brains were extracted. Immunofluorescence analysis was then performed to review the number of THir+ neurons in SNpc.

![Rotarod & Motor Activity Tests](image)

**Figure 1.** The experimental design shows the pre- and post-treatment strategies. The TL extract or Tween 80 was given to mice for 7 days before and after the MPTP inducing to be PD in the pre-treated and post-treated mouse groups, respectively. The Rotarod and Motor Activity Tests were examined in all groups on day 0, 7, 9 and 15. MPTP; the 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine, TL; Thunbergia laurifolia Lindl.

**Behavioral analysis and brain tissue preparation**

**Rotarod test.** Thirty minutes before the trial, mice of each group were selected, and were also allowed to rest before test. The mice were placed on the rotating bars of a Rotarod unit (7750, UGO BASILE). The rotation speed increased steadily at a rate of 4, 12, 19, 26, 33, and finally 40 rounds per minute. The time that the mice were spent on the rotating bar before falling down was recorded as the latency time in seconds.
**Motor activity test.** The motor activity was estimated in an automated frame box (25x25 cm², frame) containing an infrared beam (LE8825, PANLAB). One hour before the trial, the mice of each group were randomly selected and were then allowed to rest before the test. The tested mice were placed in the frame box for 15 minutes. The frequency of mouse movement was detected by beams connected to a monitor analyzer.

**Perfusion and sectioning**

Following the 15 day experimental period, the control mice and induced mice were given a lethal dose of ether and were perfused transcardially with the phosphate buffer (PB) solution, followed by a fixative of 4% paraformaldehyde, pH 7.4. After the perfusions were performed, the brains were removed from the skulls. Brains were cut into 50 µm thick coronal sections using a Vibratome (Leica 1200s). The brain sections were collected from rostral to caudal sections every 5th section in PB.

**Immunofluorescence and the labeling of the dopaminergic neurons in SNpc**

To reveal the dopaminergic neurons, one row of brain sections from three mouse brains of each group were processed by immunofluorescence. The sections were incubated in a solution of 3% hydrogen peroxide (H₂O₂) in methanol one hour to eliminate any endogenous peroxidase activity. It was then washed 3 times in 0.1 M PB for 10 minutes. The sections of each group were immersed in blocking buffer containing 10% normal goat serum (NGS), 0.1% Triton X-100 in PBS for 60 minutes and then were incubated in a solution containing the mouse monoclonal primary antibody to tyrosine hydroxylase (TH) (65106M4874V, Sigma) at a dilution of 1:1,500 at 4°C overnight. The incubated sections were subsequently rinsed 3 times in 0.1 M PB for 10 minutes and then were placed in a solution containing the goat anti-mouse IgG (H+L) secondary antibody, Rhodamine conjugate (Catalog No. 31660, Thermo Fisher) at a dilution of 1:100 for one hour. The sections were then washed in 0.1 M PB and mounted on a slide. The TH immunoreactive (THir⁺) cells in the SNpc of all groups were examined under a fluorescent microscope. The photos of THir⁺ cells in SNpc were taken. THir⁺ cells were indicated as cells containing TH antigen-antibody complexes conjugated with Rhodamine in cytoplasm and the central dark nuclei. The number of THir⁺ cells in all SNpc sections of each brain were counted using an Image J program and was presented as mean ± SD.

**Statistical analysis**

All data was presented as mean ± SD. Differences among means were analyzed using one-way analysis of variance (ANOVA) which was followed by a post-hoc analysis with a Tukey test for multiple comparisons using an R program. The values of $P < 0.05$ were considered statistically significant.
RESULTS

Effects of TL extract on MPTP induced the motor co-ordination dysfunction

The MPTP mouse models of PD demonstrate the motor behavioral defects including co-ordination. The Rotarod test was applied to mice in order to evaluate their co-ordination in terms of time spent running on the rotating rod or any latency time before falling off the rods. As shown in Figure 2, on day 0 and 7, there were no difference of co-ordination functions in all groups. On day 9, the latency times of the all MPTP induced mice had significantly reduced compared to the control ($P<0.01$ for the MPTP + pre TL and $P < 0.001$ for the rest). On day 15, there were significant differences of the latency times of the vehicle groups ($P < 0.001$) and the MPTP + post TL group ($P < 0.05$) compared to the control. The latency time in the MPTP + pre TL had significantly increased on both day 9 ($P < 0.001$) and day 15 ($P < 0.01$) when compared to the vehicle groups. Therefore, the pre-treatment of TL extract of 200 mg/kg of BW can improve the coordination of the MPTP induced mice.

Figure 2. The latency time on the rotating rod of the control, pre Tween 80, pre TL, post Tween 80, and post TL of the MPTP induced mice on day 0, 7, 9, and 15. The data of latency time (seconds) were shown as mean ± SD; n = 6. *** $P < 0.001$, ** $P < 0.01$, * $P < 0.05$ versus the control and ### $P < 0.001$, ## $P < 0.01$ versus the MPTP + pre Tween 80.
Effects of TL extract on MPTP induced deficiency in motor activity.

The frequency of movements was recorded to evaluate the motor activities of all five groups of mice. Similar to their latency time, the motor activities of all mice groups on day 0 and day 7 were not significantly different as shown in Figure 3. The motor activities of the MPTP + pre Tween 80, MPTP + post Tween 80 and MPTP + post TL groups significantly reduced on day 9 ($P < 0.001$ in all groups) and on day 15 ($P < 0.01$, $P < 0.001$, and $P < 0.05$, respectively) compared to that of the control. Obviously, the MPTP + pre TL group of mice significantly increased their motor activity on day 9 and day 15 from the pre-vehicle groups. Therefore, the pre TL treatment for the 7 day period before the MPTP inducing in mice can improve their motor movements or bradykinesia of the mouse model of PD.

The data of motor activity (times) is shown as mean ± SD; $n = 6$. *** $P < 0.001$, ** $P < 0.01$ , * $P < 0.05$ vs. the control; ## $P < 0.01$ vs. the pre Tween 80+ MPTP.

Effects of TL extract on MPTP induced dopaminergic neuron depletion.

The dopaminergic neurons in SNpc can be observed by the TH immunoreactive (THir+) cells. All MPTP induced mice showed dopaminergic neuron depletions as shown in Figure 4 A. The numbers of THir+ cells in SNpc were significantly reduced in all MPTP induced mice when compared to that of the control (Figure 4B). However, that numbers of the pre TL group was less different ($P < 0.05$) than that of the post TL group ($P < 0.01$) when compared to...
that of the control. Both pre TL and post TL groups demonstrated significant higher numbers of THir+ cells than that of their vehicle groups (P<0.001). Therefore, the degeneration of dopaminergic neurons in SNpc was due to the MPTP inducing that may be reversed by treatment with the TL extract.

**Figure 4.** (A) The SNpc sections containing the THir+ cells from the control, MPTP + pre Tween 80, MPTP + pre TL, MPTP + post Tween 80, and MPTP + post TL groups are demonstrated. Scale bars = 100 µm and was applied in all panels. (B) The data of the THir+ cells were shown as mean ± SD, n = 6. *** P<0.001, ** P<0.01, and * P<0.5 versus the control. ### P<0.001 versus the vehicle treated group. SNpc; substantia nigra pars compacta, THir+: Tyrosine hydroxylase immunoreactive.

**DISCUSSION**

This study used male C57BL/6 mice as the acute MPTP induced mouse model of PD as has been done in previous studies (Liu et al., 2014; Guo et al., 2016). The C57BL/6 mice were the mouse strain that is most sensitive to the toxic effects of MPTP compared to others (Muthane et al., 1994; Hamre et al., 1999). The MPTP was also found to be a neurodegenerative toxin in SNpc in humans (Langston et al., 1999). Our acute mouse model of PD received four IP injections of MPTP 20 mg/kg of body weight at 2 hour intervals. There was an approximately 70-80% loss of dopaminergic neurons in both MPTP + pre Tween 80 and MPTP + post Tween 80 groups. These were relatively close to the previous
studies that reported a 60-70% loss of the nigrostriatal dopaminergic neurons in the acute mouse models of PD (Jakowec et al., 2004).

The anti-oxidant and anti-inflammation properties of TL have been reported (Chan and Lim, 2006; Wonkchalee et al., 2012). Boonyarikpunchai et al. (2014) found high phenolic and flavonoid compound concentrations in the ethanol and water extraction of TL. The TL extract used in this study was ethanol extracted TL leaves. The sample of the TL ethanol extract solution contains 106.0 mg/L anti-oxidant and 290.59 µg/ml phenolic compounds. Thus, the effects of the TL treatment in a PD model used in this study could obtain results concerning their anti-oxidant properties.

This study found that the TL treatment before inducing with MPTP attenuated the motor dysfunction such as coordination and bradykenisia of the MPTP mouse model of PD more than the post TL treatment. These results are similar to a previous study which reported that rats fed with TL extract prior to cadmium explosion demonstrated less motor abnormality than those rats fed with TL extract after the cd explosion (Ruangyuttikarna et al., 2013).

Our results demonstrated that after one week of the MPTP injection, the pre-treatment strategy of TL extract in the acute MPTP significantly improved motor co-ordination and increased motor activity. On the other hand, the post-TL treatment group and the post-vehicle group did not significantly exhibit any motor behavior. This may be due to the fact that pre-treatment with TL extract on the acute MPTP induced mice might reduce the toxicity the MPTP under levels that can cause PD symptoms. Therefore, the motor improvements of MPTP models resulted from the detoxification properties of TL in MPTP toxins. The detoxification of TL was also supported by evidence of reduction of others toxins such as lead (Tangpong and Satarug, 2010), paraquat (Ussanawarong et al., 2000), and cadmium (Ruangyuttikarna et al., 2013).

The leaf TL extract was found to prevent the loss of motor and cognitive performance resulting from lead (Pb) induced neurotoxicity in a dose dependent pattern (Palipoch et al., 2011; Phyu and Tangpong, 2013), reducing the death of the hippocampal neurons of rats poisoned by lead (Tangpong and Satarug, 2010). Since our study used the TL extract at dose of 200 mg/kg BW to treat the MPTP induced mice PD models, it did not significantly alleviate the dopaminergic degeneration in both the pre- and post treatment strategies. However, the pre-treatment with the TL extract at 200 mg/BW significantly improved coordination and motor activity in these models. These findings might indicate that TL extract has protective effects on MPTP induced mouse models of PD. However, the reversed motor deficiency effects and the neuroprotective properties of the TL extract in dose dependent manners in the MPTP induced PD models need to be investigated further.
CONCLUSION

The TL extract was known for its detoxification and anti-oxidant properties. MPTP is a toxin, which is commonly used to induce PD in a mouse model. PD is caused by dopaminergic neuron degeneration that leads to motor impairments. The pre-treatment of TL extract of 200 mg/kg in the MPTP mouse PD model reversed motor impairments and increased motor co-ordination and motor activities. However, the post TL treatment did not significantly improve motor deficits. Thus, the pre-treatment of TL extract of 200 mg/kg on MPTP for 7 days can prevent motor deficiency in the MPTP induced mouse PD model.
